US-20 Application Status Tracking - Sprint 2 AI Log

Prompt 1 - Repository Analysis and Implementation Planning

Purpose of AI Use: Repository analysis, requirements clarification, and implementation planning for US-20 Application Status Tracking.

Date: October 25, 2026

AI Tool: OpenAI Codex

AI-Suggested Content: Codex inspected the existing CareerConnect repository and identified the current application flow, relevant database schema, recruiter application page, authorization logic, navigation, and tests. It identified which parts of US-20 were already supported and which parts were still missing.

Validation: The analysis was compared with GitHub issue #107 and the existing application flow in the running project. The relevant pages were manually checked using the shared recruiter and job-seeker test accounts. The analysis correctly identified that application submission and recruiter application viewing already existed, while application status storage, status controls, and the My Applications page were missing.

Decision: Accepted as an implementation plan. Offered and Rejected were intentionally kept dependent on US-03 because issue #107 requires final decisions to include an outcome message.

Reflection: Codex was useful for understanding an unfamiliar SvelteKit/TypeScript project and locating the files relevant to the user story. The output was much more detailed than needed, so the implementation plan was reviewed and reduced to the parts directly required for US-20.

Responsible Person: Kimia Karimiyeganeh

Prompt

Read this entire CareerConnect repository, but DO NOT modify any files yet.

I am responsible for US-20: Application Status Tracking, GitHub issue #107.

Requirements:

- New applications start with status "Applied".
- The recruiter who owns the job can update an application to Under Review, Interview, Offered, or Rejected.
- Other recruiters/users must not be allowed to update it.
- Offered and Rejected must integrate correctly with the outcome-message requirement from US-03.
- Job seekers need a "My Applications" page showing the job, application date, and current status.
- Tests are required.

First:

1. Inspect the existing application flow, database schema, recruiter applications page, authentication/authorization, navigation, and tests.
2. Tell me exactly which existing files are relevant.
3. Explain the current architecture to me in beginner-friendly language.
4. Tell me what is already implemented and what is still missing for US-20.
5. Give me a step-by-step implementation plan.

Do not write or modify code yet.

Response

Codex found that the existing project already supported:

- submitting and withdrawing job applications;
- recruiter viewing of applications for jobs they own;
- authorization based on job ownership;
- five application status labels defined in the project.

Codex identified the following missing parts for US-20:

- persistent application status in the database;
- recruiter controls for updating status;
- server-side status-update authorization;
- a My Applications page for job seekers;
- navigation to My Applications;
- US-20-specific tests.

Codex also identified that Offered and Rejected should not bypass US-03 because final decisions require an outcome message.

Prompt 2 - US-20 Implementation

Purpose of AI Use: Code generation and automated validation for the US-20 implementation.

Date: October 25, 2026

AI Tool: OpenAI Codex

AI-Suggested Content: Codex modified the application schema, recruiter application page and server actions, navigation, and created a My Applications page and US-20 tests. It implemented Applied as the default status and permitted normal recruiter updates to Under Review and Interview while reserving Offered and Rejected for the US-03 outcome-message flow.

Validation: All generated changes were reviewed before committing. Codex ran the project's automated tests and type checks successfully. The generated Git diff was reviewed file-by-file. The shared Supabase database was inspected before applying any schema change. A broad `db:push` was cancelled because it detected unrelated schema differences, and only the required `status` column and allowed-status constraint were added manually through Supabase SQL. The feature was then manually tested using both recruiter and job-seeker test accounts. Applied, Under Review, and Interview were confirmed to display correctly and persist after refreshing. The My Applications page correctly displayed the job, company, application date, and current status.

Decision: Accepted with review and manual database adjustment. The generated application-status functionality was retained. Offered and Rejected were deliberately excluded from the normal dropdown because they are integrated through US-03.

Reflection: Codex significantly reduced the time required to implement a feature in an unfamiliar framework. However, its generated code and suggested database operations still required human review. In particular, blindly synchronizing the full local schema with the shared database could have affected unrelated team work, so only the required database change was applied. Manual testing was necessary to verify that the status changes worked correctly for both recruiter and job-seeker users.

Responsible Person: Kimia Karimiyeganeh

Prompt

Implement US-20 on my current feature/application-status branch.

You may edit the local repository files yourself.

Important constraints:

- Do NOT push anything to GitHub.
- Do NOT commit anything yet.
- Do NOT modify main.
- Do NOT run db or make destructive changes to the shared Supabase database without asking me first.
- Keep changes limited to US-20 and avoid unrelated refactoring.
- Reuse the existing project style and patterns.
- Keep the implementation simple and appropriate for this university project.

Implement:

1. Add application status storage with default "applied".
2. Add recruiter controls to change status to Under Review or Interview.

3. Enforce server-side authorization so only the recruiter who owns that job can change its applications.
4. Display the current status on the recruiter Applications page.
5. Create a job-seeker "My Applications" page showing job, application date, and current status.
6. Add "My Applications" to job-seeker navigation.
7. Add appropriate US-20 tests.

For Offered and Rejected:

- Do NOT create a fake or duplicate US-03 outcome-message system.
- Preserve the requirement that Offered/Rejected must go through US-03.
- Prevent the ordinary status update action from directly setting Offered or Rejected.
- Clearly tell me what remains dependent on US-03 after your implementation.

After editing:

- Show me a concise summary of every file you changed and why.
- Run the appropriate non-destructive tests.
- Tell me about any failing tests or blockers.
- Do not commit, push, or modify the shared database.

Response

Codex implemented US-20 across seven files.

The implementation:

- added a status field to applications with Applied as the default;
- limited stored values to Applied, Under Review, Interview, Offered, and Rejected;
- displayed application status to recruiters;
- allowed the recruiter who owns a posting to change an application to Under Review or Interview;
- added server-side ownership and role checks;
- prevented Offered and Rejected from being set through the ordinary status action;
- created a My Applications page for job seekers;
- added My Applications to job-seeker navigation;
- added automated tests for status defaults, authorization, invalid statuses, ownership, My Applications filtering, and empty states.

Codex reported that the automated test suite passed and the project type check completed without errors. No files were committed or pushed automatically, and the shared database was not modified by Codex.
